

Few-Shot Learning with Localization in Realistic Settings

(Supplementary Materials)

Note: Code for the models and main results of the paper are available at <https://github.com/daviswer/fewshotlocal>.

1. Additional Results

1.1. Ablation Study

Top-1 and top-5 mean and per-class accuracies are given below. Three-digit model names indicate the presence or absence of batch folding, localization, and covariance pooling, in that order. For example, ‘101’ indicates a model with batch folding and covariance pooling, but no localization. Because two versions of localization exist, we use ‘0’ to indicate no localization, ‘1’ for few-shot localization, and ‘2’ for unsupervised localization. A ‘*’ indicates a model presented in the main paper.

Model	Top-1 Accuracy		Top-5 Accuracy	
	Mean	Per-Class	Mean	Per-Class
000*	16.07 ± .19	17.55 ± .19	42.10 ± .21	41.98 ± .18
100*	20.04 ± .04	20.81 ± .08	47.86 ± .31	46.57 ± .23
010	21.55 ± .09	22.37 ± .08	50.20 ± .08	48.70 ± .08
001	24.31 ± .48	24.64 ± .39	53.29 ± .76	51.09 ± .63
020	24.32 ± .15	24.68 ± .81	53.16 ± .89	51.44 ± .94
021	25.60 ± 1.02	25.51 ± .90	54.66 ± 1.07	52.04 ± .91
110*	26.25 ± .05	26.29 ± .04	55.43 ± .09	53.01 ± .08
011	27.46 ± .15	26.39 ± .14	56.37 ± .17	52.37 ± .17
120*	28.75 ± .13	28.39 ± .15	57.90 ± .24	55.27 ± .37
101	31.06 ± .61	29.07 ± .53	60.41 ± .67	55.50 ± .62
121*	32.74 ± .13	30.52 ± .13	61.32 ± .14	56.62 ± .16
111*	35.52 ± .05	31.69 ± .06	63.76 ± .09	57.33 ± .10

Between any two models with different numbers of features, the one with more always outperforms the one with less, regardless of combination. Thus batch folding, localization, and covariance pooling consistently and independently improve performance on meta-iNat.

1.2. Learning Without Forgetting

We evaluate the ability of our prototype-styled classifiers to adapt to new concepts without forgetting old ones. We combine the evaluation and representation sets of meta-iNat into a single, larger dataset and provide accuracy numbers for prototype-styled classifiers. Softmax classifiers are ignored, as they cannot handle old and new concepts simultaneously without completely replacing the topmost fully-connected layer. While accuracy decreases overall (we are now distinguishing between 1135 categories rather than 227), batch folding, few-shot localization, and covariance pooling still lead to significant improvements. For logistical reasons, we run only one trial in all settings, though we still evaluate four independently trained models for each.

Model	Top-1 Accuracy		Top-5 Accuracy	
	Mean	Per-Class	Mean	Per-Class
Baseline	6.64 ± .06	7.37 ± .08	21.08 ± .13	21.08 ± .19
Batch Folding	8.87 ± .13	9.35 ± .14	25.92 ± .20	25.13 ± .16
BF + few-shot localization	13.22 ± .04	13.11 ± .07	33.54 ± .12	31.60 ± .12
BF + fsL + covariance pooling	20.69 ± .16	17.44 ± .13	43.70 ± .23	37.17 ± .33

2. Network Architectures

Our learner architectures mimic the original prototypical networks. Networks contain four 64-channel 3×3 convolutional layers, with Batchnorm, ReLU, and 2×2 max-pooling in between. This is followed by Batchnorm and 10×10 global

average-pooling, for a 64-dimensional feature vector. Unlike prototypical networks, which flatten the feature map to a 6400-dimensional vector, we use average pooling to eliminate spatial priors on uncentered, uncropped images. Softmax classifier models use a fully-connected layer on top of the feature vector; prototype classifiers use the feature vector directly. Localization and covariance pooling models replace average-pooling layers with the appropriate algorithm(s).

Models based on ResNet50 use the first two stages of a ResNet50 model, pretrained on ImageNet, to produce 28×28 feature maps with 512 channels. Learned layers consist of 2×2 max-pooling, followed by 3×3 convolution with 128 channels, Batchnorm, ReLU, a second 3×3 convolution with 64 channels, and Batchnorm. The resulting 14×14 feature maps are localized, average pooled, or covariance pooled as appropriate. As in the original setting, softmax classifiers use an additional fully-connected layer, while prototype architectures use the pooled embeddings directly.

3. Training and Implementation Details

3.1. Training

We train meta-iNat models via SGD with Adam, using an initial learning rate of 10^{-3} and dividing by two every epoch. Each epoch consists of 10 passes over the representation set, with five epochs in total. For mini-ImageNet, we lengthen each epoch to 28 passes, to account for the smaller representation set.

In both settings we unit-normalize input color channels. We use random horizontal flipping but no other data augmentation. Because bounding boxes are downsized to very small resolutions (e.g. 10×10), we use 4×4 average-pooling before downsampling, as a fast approximation for anti-aliasing.

3.2. Batch Sampling

While mini-ImageNet uses random batch sampling with replacement during training and testing, meta-iNat uses a different sampling procedure for each. During each training iteration, classes are sampled without replacement: so long as classes have sufficient remaining images to create a batch, they are sampled proportionately to the number of available images they contain. This ensures that differently-sized classes occur at constant, representative rates throughout the entire sampling process. Images are then selected from the sampled classes, and those images are subsequently unavailable for further training until the next pass over the dataset.

During testing, we wish to evaluate classification accuracy for relatively large numbers of classes and images. For sufficiently high values, it becomes impossible to process the sampled datasets as single batches in computer memory. Category sizes also vary so widely that it no longer makes sense to use constant sample sizes. Rather than attempt to evaluate a given network on a large number of large and complicated datasets, we instead impose a single reference/query split over the evaluation set.

Evaluation consists of one pass over the reference images followed by one pass over the query images. During the reference pass, each category is split into manageable batches, and the class centroid is computed from a running total of the embedding vectors. The query pass is divided the same way, and the pre-computed centroids are used to make class predictions. When localization is used, we run 10 trials where different 10% subsets of the reference images are randomly selected to receive bounding box annotations.

The above applies to prototype-styled classifiers, which require representation and query sets for a limited selection of classes in every batch. For straightforward softmax classifiers, we instead use random sampling without replacement, and a batch size of 128. Annealing schedule is as above.

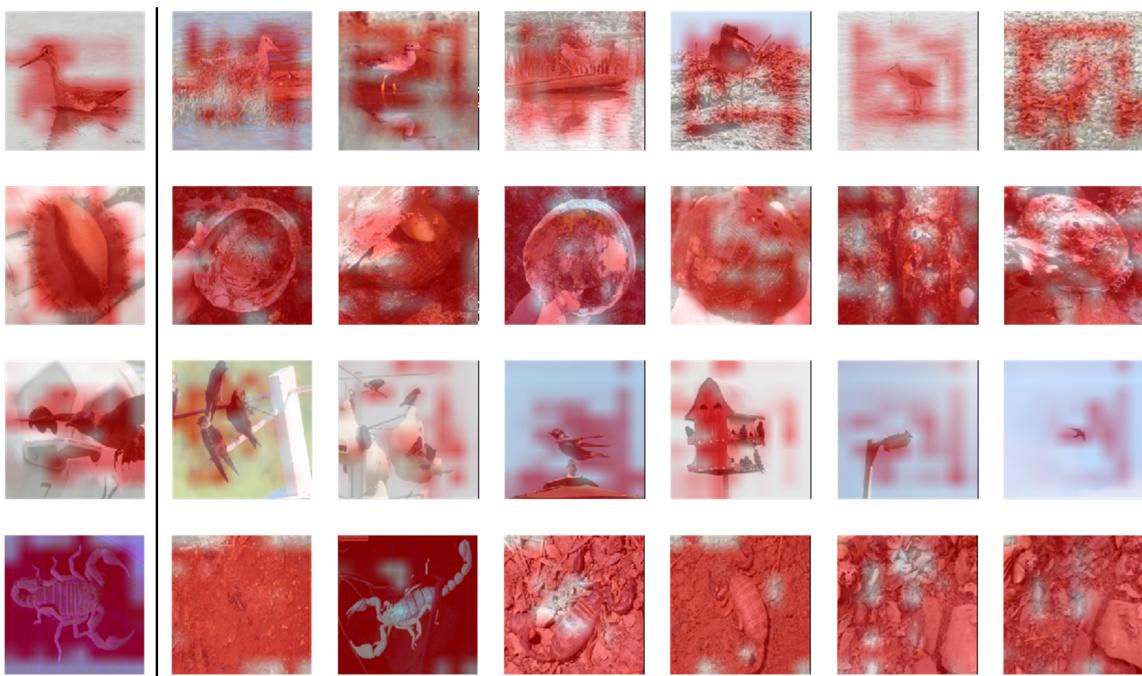

4. Additional Few-Shot Localization Examples

When individual bounding boxes in the annotated reference image are small, localization tends to work well, given the model's lack of power (a four-layer network with 10×10 outputs and no localization supervision). The leftmost image provides the ground truth bounding box(es).

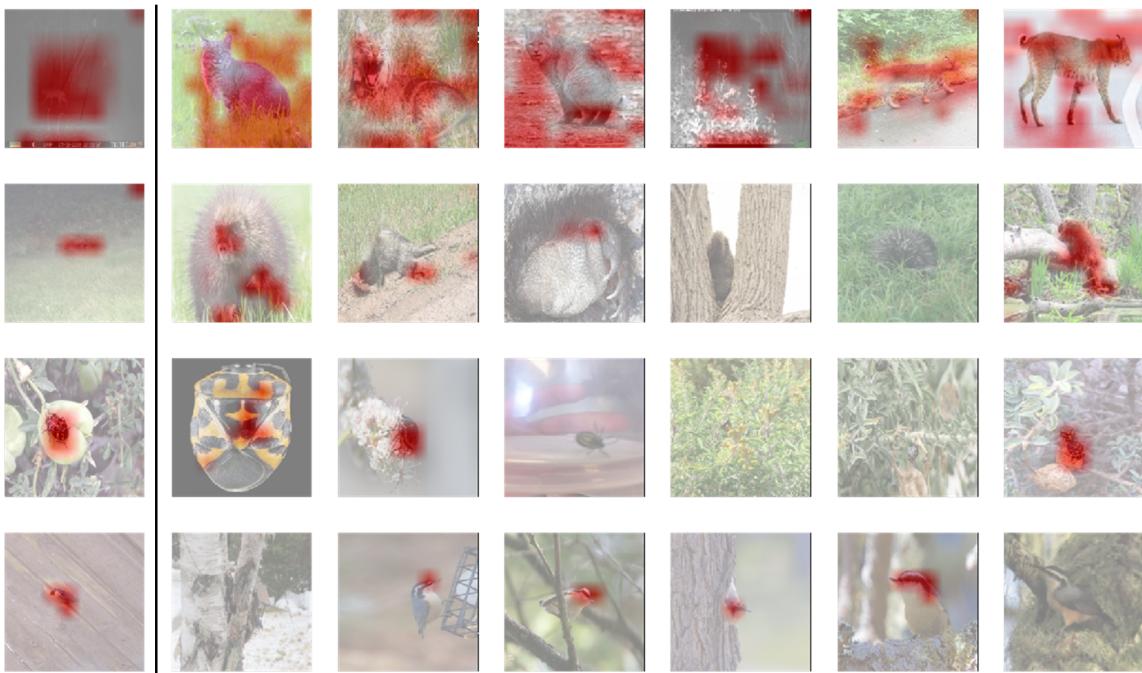

4.1. Failure cases

When bounding boxes in the annotated reference image are too large or too small, localizer performance breaks down. In the former case, too much of the background is included in the bounding box, and the localizer becomes over-inclusive.

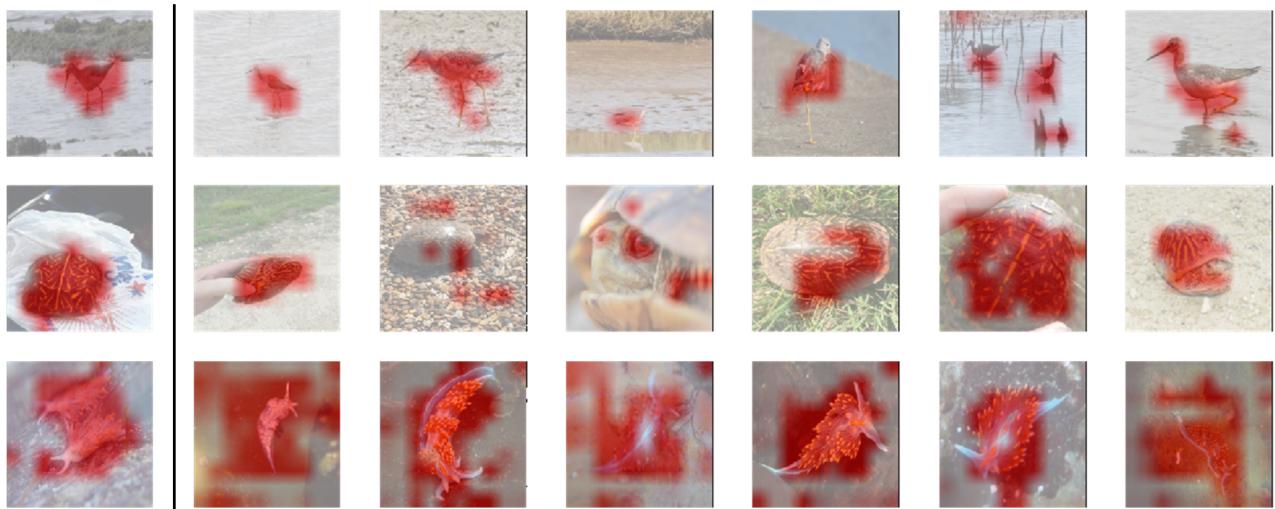

When bounding boxes are too small, the localizer focuses on the wrong things, selects small parts of the object in question, or in some cases fails to detect a region of interest at all.

4.2. Additional annotations

Localizer performance generally improves as more annotations are made available.

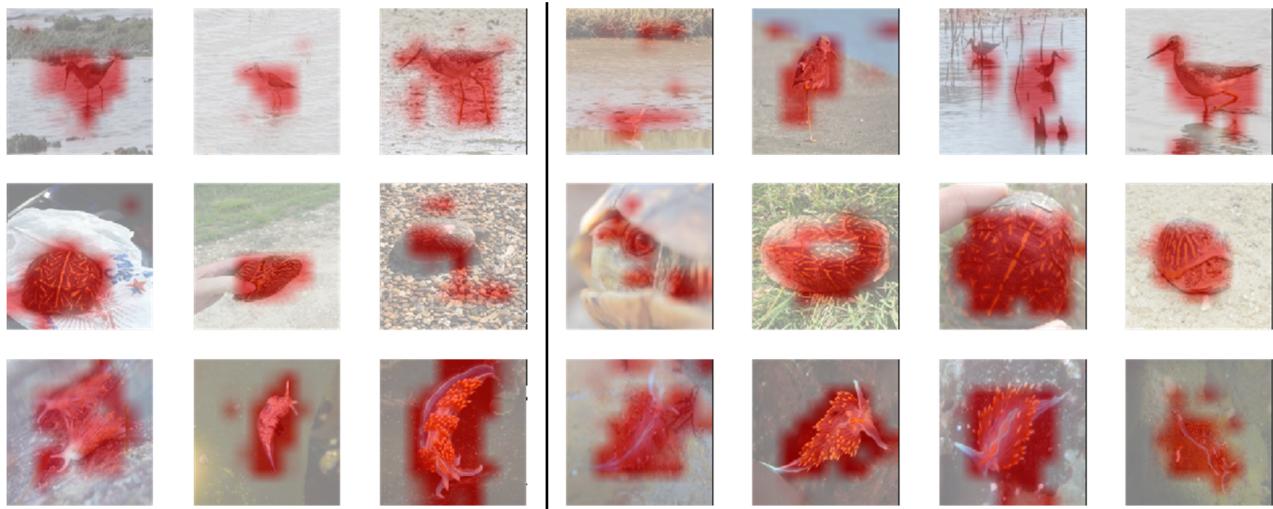

One annotation per row: The localizer often selects only parts of the relevant object, or includes significant portions of the background.

Two annotations per row: The localizer has eliminated much of the irrelevant background areas from its predictions, increasing precision (see bottom row in particular), as well as including more of the relevant object.

Three annotations per row: The localizer includes larger portions for photos where it originally selected only a small subregion, improving recall (see middle row in particular).

5. Meta-iNat Category Splits

The code for meta-iNat is available on GitHub, but we list the category assignments here for the sake of completeness.

Evaluation Categories

Arachnida/Nephila clavipes	Aves/Cygnus columbianus	Aves/Sialia currucoides
